COMBINED FOUNDATION (page 1 of 2)**

Photosynthesis

Photosynthesis is a chemical reaction that occurs in chloroplasts in plants and algae to produce glucose. It is represented by this equation:

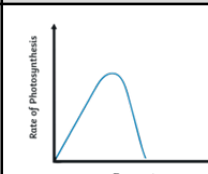

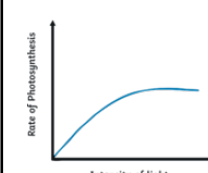

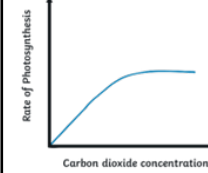

Photosynthesis is an endothermic reaction as light energy is transferred from the environment to the chloroplasts by light.

The glucose produced in photosynthesis may be:

- Used for respiration
- Converted into insoluble starch for storage
- Used to produce fats or oils for storage
- Used to build cellulose, which strengthens plant cell walls
- Make amino acids by combining with nitrates. The amino acids are then used to build proteins.

Factors affecting the rate of photosynthesis (required practical 6)

| Factor | Effect on the rate of photosynthesis | Graph |
|-------------------------------------|--|---|
| temperature | Photosynthesis is controlled by an enzyme. As the temperature increases so does the rate of photosynthesis, up until a certain point. If the temperature gets too high then the enzyme will be denatured and the rate of reaction with decrease. |  |
| light intensity | As light intensity increases so does the rate of photosynthesis, until something else becomes the limiting factor (when the graph curve flattens) |  |
| carbon dioxide concentration | As carbon dioxide concentration increases so does the rate of photosynthesis, until something else becomes the limiting factor (when the graph curve flattens) |  |
| amount of chlorophyll | Chlorophyll is the green pigment inside chloroplasts that absorbs light energy. The more chlorophyll a plant has, the quicker photosynthesis can occur. | |

Identifying limiting factors on graphs

A limiting factor is something that is limiting the rate of photosynthesis e.g. if there isn't enough light for the reaction to occur, light is the limiting factor.

As the intensity of light increases, so does the rate of photosynthesis. This means light is the limiting factor

The graph levels out when increasing the light intensity no longer increases the rate of photosynthesis. This means light is no longer the limiting factor. Something else is limiting the reaction such as temperature of carbon dioxide concentration.

COMBINED FOUNDATION (page 2 of 2)

Respiration

Respiration is a chemical reaction that occurs in all living cells. Respiration transfers the energy needed for the processes of living things. As it releases energy to the surroundings, it is an exothermic reaction.

Organisms need energy for:

1. Chemical reactions to build large molecules
2. Movement (muscle contraction)
3. Keeping warm (respiration releases thermal energy)

Types of respiration

| Type of respiration | Equation | Description |
|--|---|---|
| aerobic respiration | glucose + oxygen → carbon dioxide + water $C_6H_{12}O_6 + O_2 \rightarrow CO_2 + H_2O$ | Respiration that uses oxygen and occurs in mitochondria of cells. Releases a lot of energy |
| anaerobic respiration (muscles) | glucose → lactic acid | Respiration when oxygen is in short supply during intensive exercise. Releases less energy than aerobic respiration. Lactic acid builds up and causes muscles to become fatigued and prevents the muscles stop contracting efficiently. |
| fermentation | glucose → ethanol + carbon dioxide | Anaerobic respiration that occurs in microorganisms, e.g. yeast. Carbon dioxide is used to make bread rise and ethanol is used to make alcoholic drinks |

Response to exercise

During exercise your body requires more energy and therefore needs to respire more. In order for more respiration to occur your cells must be supplied with more oxygen or glucose. Your body does this by responding in the following ways

| Response | Benefit |
|----------------------------------|--|
| Heart rate increase | This increases the blood flow to muscles and supplies them with more oxygen and glucose. This also increases the rate that carbon dioxide is removed from muscles. |
| Breathing rate increases | Increases the amount of oxygen getting into your bloodstream |
| Breathe more deeply | Increases the amount of oxygen getting into your bloodstream |
| Arteries to muscles dilate | This means that arteries get wider to increase the blood flow to muscles and supply them with more oxygen and glucose. |
| Glycogen is converted to glucose | Supplies muscle cells with more glucose |

Metabolism

Metabolism is the sum of all the reactions in a cell or the body. Metabolic rate is how quickly these reactions occur. The energy transferred by respiration in cells is used for many enzyme controlled metabolic reactions that synthesise new molecules.

Some examples of metabolic reactions include:

- Respiration
- Converting glucose to starch, cellulose or glycogen
- Forming lipids from glycerol and fatty acids
- Forming amino acids from glucose and nitrates
- Breakdown of excess proteins to form urea
