

AQA B7a – Ecology: Adaptations COMBINED HIGHER

Key word	Definition
Environment	The biotic and abiotic conditions that surround an organism
Habitat	The place where organisms live
Population	Individuals of one species that live in a particular habitat
Community	Populations of different species that live in a particular habitat
Ecology	The study of living things in their environment
Ecosystem	The interaction of a community of organisms (biotic) with the non-living (abiotic) parts of their environment
Organism	An individual living thing
Adaptations	Features that allow organisms to survive in the conditions in which they normally live

Examples of biotic and abiotic factors

Biotic – living factors that affect a community	Abiotic – non-living factors that affect a community
<ul style="list-style-type: none"> • Temperature • Light intensity • Moisture levels • Soil pH • Wind intensity and direction 	<ul style="list-style-type: none"> • Carbon dioxide levels for a plant • Oxygen levels for aquatic animals • Availability of food • Predation • New pathogens • Competition – one species outcompetes another

Types of adaptations

	Structural	Behavioural	Functional
Definition	Features of an organism's body e.g. shape, colour	The way an organism behaves e.g. migration, hibernation	Things happening inside an organism e.g. reproduction, metabolic rate
Examples	Polar bears live in the arctic so have white fur to camouflage against the snow	Many bears hibernate over the winter. This lowers their metabolism, reducing need for hunting for energy when there is least food.	Desert animals such as camels produce very little urine to conserve water in a very dry habitat

Extremophiles are organisms which live in very extreme environments such as high temperature, pressure or salt concentration. Examples are bacteria which live in deep sea vents.

Interdependence and competition

	Interdependence	Competition
Description	Species depend on each other in many ways: for food, pollination, seed dispersal. Removing a species can affect the whole community	Plants in a community or habitat compete with each other for many things: light, air, water, space and minerals Animals also compete; for food, mates and territory
Examples	Climate change leads to more carbon dioxide dissolved in the oceans, lowering the pH of the ocean, negatively affecting the organisms that live there.	Grey squirrels were introduced to the UK in the 1800s. This increased competition for food with the native red squirrels.

Photosynthetic organisms are the producers of biomass for life on earth.

Feeding relationships can be represented by food chains that all start with a producer

Consumers that kill and eat other animals are **predators**.
Consumers that are killed and eaten by other animals are **prey**.

In a stable community, the number of predators and prey rise and fall in cycles

All materials in the living world are recycled to provide building blocks for future organisms

Microorganisms cycle materials by returning carbon to the atmosphere as CO₂ and mineral ions to the soil.

RP9 – Measure the population size of a common species in a habitat. Use sampling techniques to investigate the effect of a factor on the distribution of this species

A range of experimental measures using **transects** and **quadrats** are used by ecologists to determine the distribution and abundance of species in an ecosystem

Quadrats – Organisms are counted within a randomly placed square

Transect – Organisms are counted along a line
