

## Finding the mass of one chemical from the mass of another (mole calculations!)

By calculating the number of moles of one chemical, we can use the mole ratio from the balanced chemical equation to calculate the number of moles of another chemical. From this we can find the mass we need or would expect to produce. These calculations have three steps:

1 - Find the moles. 2 - Use mole ratios. 3 - Answer the question.

**Note** – it is useful to keep track of the moles by writing them under the balanced equation

2 NaCl

126 g of magnesium carbonate thermally decomposed 69 g of sodium was reacted with chlorine gas to forming magnesium oxide and carbon dioxide. What make sodium chloride. What mass of chlorine gas mass of magnesium oxide was produced? was needed for the reaction?  $MgCO_3 \rightarrow MgO + CO_2$ 

2 Na + 
$$Cl_2 \rightarrow 2$$
 NaCl

moles =  $\frac{\text{mass}}{M_r}$  M<sub>r</sub> of MgCO<sub>3</sub> = 84 (see page 1!) moles  $MgCO_3 = \frac{126}{84} = 1.5$  mol

moles =

moles Na =  $\frac{69}{22}$  = 3 mol

moles =  $\frac{\text{mass}}{M_r}$   $M_r$  of Na = 23

ratio  $MgCO_3$ : MgO = 1:1moles MgCO<sub>3</sub> = 1.5 mol

 $mass = moles \times M_r$ 

 $M_r$  of MgO = 24 + 16 = 40

 $mass = 1.5 \times 40 = 60 g$ 

Example

1. Find the

mole ratios

Ose

**Answer the** 

'n

question

ratio Na :  $Cl_2 = 2 : 1$ moles Cl<sub>2</sub> = 1.5 mol

moles =

 $mass = moles \times M_r$ 

 $M_r$  of  $Cl_2 = 2 \times 35.5 = 71$ 

 $mass = 1.5 \times 71 = 142 g$ 

of carbon

oxygen

excess

carbon

carbon

## **Excess and limiting reactants**

x 1

Chemists often use an excess of one reactant to make sure that all of the other reactant is used up. The reactant which is used up is called the limiting reactant as this limits the amount of product formed in the reaction. We have to use the moles of the limiting reactant to calculate the moles of product that we could make.
